

DIAMOND HANDS HOLDING INC.

TO: Jake Bulim, Evan Battaglia, John Smith, Steve Smith, Katie Tylerr
FROM: Ethan Byrd, Cybersecurity Compliance Consultants
SUBJECT: SIEM Tool Report on Experience
DATE: November 17, 2025

Dear Executives and Stakeholders,

This memorandum will be attached to a report I have written up compiling my hands on experience with the WitFoo SIEM tool and the demonstration I did in the sandbox environment. This report will summarize my key findings and highlight the significance this tool carries in day-to-day operations at Diamond Hands Holding Inc. (DHHI). I will go over the platform's main capabilities such as, centralized log aggregation, automated event correlation, and even visual event incident reporting. During my time testing the WitFoo program in the sandbox, I gained real world insight on how the SIEM tool takes incoming data, applies previous knowledge with treat intelligence, and sorts these alerts into different action items to pursue.

In conjunction with the overview of the tools technological capabilities, I have also provided you with information regarding the tools costs, and weighing that cost against the pros and cons that it provides. I go into detail regarding licensing, compliance to DHHI's standards, and overall response efficiency. Both the information I provide on the technological capabilities and the implementation led me to believe that the WitFoo Precinct SIEM tool would be a great addition to DHHI, especially with our upcoming expansion which will require a constant stream of high-log volume.

I hope the knowledge I bring forth from this report will help the company immensely in locating a new tool to use at DHHI. If this report and tool are up to standard, I would love to find a time to meet and discuss next steps for implementing the WitFoo SIEM tool into the company's tech stack. Please reach out if you have any questions.

Sincerely,

Ethan Byrd

SIEM Experience Report

REPORT OF FINDINGS

Ethan Byrd

LAST REVISED November 2025

Summary

WitFoo Precinct is a cutting edge modern SIEM, and security operations tool designed to assist cybersecurity teams in simplifying threat detection, investigation, and incident response. Unlike previous SIEMs that focus more on log storage and searching, Precinct is built around overall operational and cost efficiency, along with clear visibility of what is going on, filling the need for an organization's entire security stack.

All of this is accomplished via its interactive and in-depth dashboards and visuals, which enables analysts with even more tools to filter through logs, allowing for analysts to create a well formulated investigation into security breaches and incidents. The demonstration walked through each visualization and tab, allowing analysts to grasp the executive summary, operations efficiency, tool effectiveness, compliance readiness and cost/savings. These insights were crucial in understanding how to implement this tool into DHHI and know how we can use it to strengthen our risk stance.

The key takeaway I got from this demonstration of Precinct was that its main value does not lie in its data collection, but its ability to take that data collection and convert it into action items in the form of investigation ready cases for the analyst. These action items provide analysts with the structure needed to triage, contain, and document different incidents. Building on previous documents, such as the Security Services plan, WitFoo Precinct also uses templated standards such as NIST, which will help DHHI continue to build on that foundation that has been laid by NIST. Overall, the demonstration not only solidified the overall knowledge of SIEM tools but showed how a confusing tool can be converted into an easy to understand, proactive and helpful platform for the company.

Scope of Analysis

The scope of this evaluation for WitFoo Precinct 6.2 Demonstrator and WitFoo Sandbox will include both an observational and interactive component. The analysis started by accessing the live demonstration dashboard, where we learned how event data was taken and compiled from multiple log sources. From here I observed system messages originating from endpoint protection tools, firewall alerts, and authentication logs flowing into a centralized database.

From this hands-on demonstration in the sandbox session, I was able to perform several analytical tasks pertaining to different events and incidents:

- **Event Summary and Filtering:** With the demonstration I reviewed real-time events at 1:00 AM. We filtered through these streams using severity, IP source, and timestamp. These filters helped us to single out critical alerts or any other incidents.

- **Brute Force Testing:** I was able to simulate a brute force attack scenario by triggering multiple login attempts that all failed. Precinct automatically filtered these events under a section called “Brute Force Authentication Attempt”. This demonstrated the SIEMs ability to leak different actions to a certain case for further investigation.
- **Precinct Navigation:** Throughout the demonstration we navigated from different pages interface sections to understand how accessible it will be to analysts.
- **Playbook Execution:** I was able to trigger a sample containment playbook directly from the Incidents tab, which simulated different automated actions such as blocking offending IP addresses at the firewall and then notifying the SOC queue.
- **Investigative Report:** I was able to promote an incident to a full investigation, add notes to it as an analyst, and then export the completed investigation packing, which included a timeline, enrichments, and compiled evidence as a PDF for documentation, sharing, and reporting.

Following along with the demonstration provided me with practical knowledge into the usage and implementation of WitFoo Precinct and how it handles data, and what an analyst can do with that data, and how that cohesion between SIEM tool and analyst will provide profound exports used for documentation and reporting. It also helped enforce things that have been taught in the classroom into the real world, reinforcing those frameworks and ideals we have been taught for the last year.

Cost of Benefits

Like all modern tools, WitFoo Precinct comes with different cost models based on the needs of the company. The operational advantages Precinct provides also comes with their own upfront substantial costs which need to be taken into consideration.

Primary Costs

- **Subscription based-service:** Precinct is a Cloud based SaaS model which charges events-per-second (EPS), which can scale quickly with DHHI's large data influx.
- **Storage:** Has built in cloud storage with incremental feeds for added storage.
- **Implementation:** Combining current security tools with Precinct may require the need of a third-party consultant to ensure support and a smooth transition.
- **Training:** SOC team and analysts must be trained in Precinct on how to translate the data and visuals into documentation and reports for other team members and executives.
- **Maintenance:** Precinct will require its own set of updates and maintaining if run on-premises, or if certain actions are not being caught, there will need to be some finetuning in the dashboard to fix these issues.

Key Benefits

- **Scalability:** With Precinct being elastic and scalable, traffic spikes or increased data inflow would be handled easily without having to expand servers or hardware.
- **Compliance Automation:** To speed up the process of reporting and documentation, Precinct allows analysts to generate reports based on different frameworks such as NIST, PCI, and HIPAA in under two minutes.
- **Automated Analysis:** Reduces overhead time and cost of log review time, allowing for analysts to allocate themselves to more important tasks and projects.
- **Centralized Network:** All network activity and streams are consolidated to Precinct, allowing for a reduction in blind spots and improved anomaly detection and reduced false positives.

Due to DHHI's large influx of data, WitFoo Precinct will be more expensive than previously used or reviewed SIEM tools. The value it brings to the team and organization will greatly outweigh the newly added costs. A reduction in time, overhead, and incidents will allow for a stronger risk stance and overall reduced capital.

Recommendations

Based on the findings from my technical, operational, and cost report on the WitFoo Precinct SIEM platform, moving forward I will be recommending DHHI integrate this into their company. This is largely due to DHHI's large inflow of data, which requires a SIEM tool that can not only handle that, but convert that data into digestible information via the figures you see above. With DHHI already having a designated Security Operations Center (SOC) team, this tool will mainstream that process even further with the usage of incident report, and NIST documentation frameworks.

If DHHI did not have a designated SOC team or wished for this tool to be used for a lower tier analyst, I would still recommend this tool but a smaller deployment model would be more effective. Implementing a cloud-based, or even hybrid model could help reduce those costs if only a smaller team will be using the tool while still maintaining all the necessary tools and visualizations.

At the end of the day, WitFoo Precinct is not just your average SIEM tool, and it does not make you file through hundreds of logs with little to no information on incidents, it provides readily responsive information, recommendations and documentation on logs, incidents, and threats. Its ability to take all of that information and convert it into digestible visualization and tables, while maintaining a cost-effective implementation, make it a worthwhile investment for DHHI's risk stance.
